

Problem Set 2 - for Week 2

1. Assume that the energy scale of inflation is  $10^{15}\text{GeV}$ . How long (in units of  $H^{-1}$ ) does the period of inflation have to be
  - a) in order to solve the horizon problem
  - b) in order to solve the flatness problem
  - c) in order to solve the structure formation problem.

Assume that  $H$  is constant during the period of inflation.

2. Based on the action principle, derive the equation of motion of a real scalar field in a Friedmann-Robertson-Walker-Lemaitre universe.

3. Consider the Klein-Gordon equation in a FRWL background, and consider linearized fluctuations about a homogeneous solution  $\varphi_0(t)$ . Each Fourier mode of the fluctuations evolves independently. Find approximate solutions for sub-Hubble ( $k \gg H$ ) and super-Hubble ( $k \ll H$ ) modes.

4. Derive the energy-momentum tensor of a real scalar field in a FRWL background, and derive the expressions for the energy density and pressure.

5. Consider the new inflationary scenario with potential

$$V(\varphi) = \frac{1}{4}(\varphi^2 - \eta^2)^2$$

- . For which values of  $|\varphi|$  are the slow-roll criteria satisfied?

6. Consider the same problem for a chaotic inflation model with potential

$$V(\varphi) = \frac{1}{2}m^2\varphi^2.$$
